

DERMATOLOGY PROGRESS NOTE

Follow-up visit · Established patient

Patient Marcus Ellison · 54M · DOB 1971-06-18
Patient ID PT-4471002
Primary diagnosis L40.0 · Psoriasis vulgaris (moderate-to-severe plaque)

SUBJECTIVE

The patient returns for follow-up of moderate-to-severe plaque psoriasis, first diagnosed 26 months ago. He reports plaques on the trunk, both extensor forearms, and both shins that have not improved since the last visit. Pruritus wakes him most nights and he rates it 7 out of 10. He completed 16 weeks of methotrexate 20 mg weekly ending 2026-02-24 with no meaningful change and stopped it on my instruction for lack of efficacy. He denies fever, joint pain, morning stiffness, and gastrointestinal symptoms. He has not travelled outside the United States in the past two years.

OBJECTIVE

Well-appearing man in no distress. Skin examination shows well-demarcated erythematous plaques with adherent silvery scale over the trunk, bilateral extensor forearms, and bilateral shins. Body surface area involvement measures 18 percent by palm method. PASI is 16.4 (erythema 3, induration 3, desquamation 3 averaged across regions). No nail pitting or onycholysis. No joint swelling or tenderness. No lymphadenopathy.

ASSESSMENT

Moderate-to-severe plaque psoriasis, L40.0, refractory to conventional systemic therapy and to narrowband UVB phototherapy. Body surface area 18 percent, PASI 16.4, DLQI 17. No clinically meaningful improvement on a completed 16 week methotrexate trial at a therapeutic dose. No contraindication to biologic therapy identified. Tuberculosis and hepatitis screening negative on 2026-07-18.

PLAN

Initiate Velunexa (velunekimab) 150 mg subcutaneously at weeks 0 and 4, then every 12 weeks. Enroll through ArvelisConnect for benefits investigation and prior authorization. Nurse injection training at first dose. Continue topical clobetasol as needed for breakthrough plaques. Recheck PASI and body surface area in 12 weeks. Repeat tuberculosis screening annually.
